

ELECTRICAL SYSTEMS

IGNITION SYSTEM (1974-80)

1. The ignition system consists of a single set of points, a condenser, and the ignition coil. The coil has two leads—one for each plug—and the cylinders therefore fire at the same time. However, since only one cylinder is on the compression stroke at any time, there is a waste spark at the other cylinder.

2. Since the two plug leads are interdependent (one connected to each end of the secondary coil), disconnecting one lead will result in a lack of spark at both cylinders. Therefore, if one plug is dirty, fouled, or defective, neither cylinder will have spark.

3. If there is no spark, and common items such as fuse, plugs, points, and wiring connections have been checked, remove the plug caps and check for spark by grounding the leads against the cylinder head. If there is spark, one or both of the caps is defective. Replace both.

4. Check the condenser. If the proper test equipment is available, the condenser should read 0.22 mfd. Alternately, check the condition of the points. Pitting, a burned-looking condition, or rounded and matching depressions are signs of arcing which is caused by a defective condenser. Replace both points and condenser if these conditions are noted.

5. Check the condition of the ignition coil primary winding by disconnecting the two primary winding leads and checking resistance across them (blue and red/yellow). Resistance should be 3.8-4.2 ohms.

6. If the primary winding is within these limits, check the secondary winding by measuring resistance across the two spark plug leads. It should be approximately 13K ohms.

7. If either of these tests indicates a resistance not within the given specifications, replace the coil.

IGNITION SYSTEM (1981 AND LATER)

These models use a transistorized ignition system replacing the breaker points of earlier years.

1. If ignition problems arise, first be sure that all wiring is in good order, connections tight and clean, etc.

2. Ignition timing is not adjusted, but the mechanical timing advance mechanism behind the pickup coil is the same as on earlier models. Be sure that the mechanism is clean and free to move the balance weights. Check that the springs are in good condition.

3. To check the pickup coil, remove the gas tank and disconnect the leads. Check that there is infinite resistance between either lead and the chassis. Check the resistance between the leads is 360-540 ohms.

4. The ignition coil can be checked as outlined for 1974-80 models, above.

CHARGING SYSTEM

The charging system consists of the alternator, rectifier, and regulator.

Alternator

1. Before carrying out the following alternator output test, be sure that the battery is

Ignition circuit wiring

fully charged. A low or defective battery will cause misleading readings. If the battery will not hold a full charge, replace it.

2. Remove the left sidecover and the headlight. Disconnect the 6-wire connector beneath the sidecover and the 9-wire connector in the headlight shell. Disconnect the white rectifier lead from the battery positive lead.

3. Set a DC voltmeter to the 30v range. Connect the positive meter lead to the rectifier white lead and the negative meter lead to ground on the frame.

4. Remove the right sidecover. Disconnect the green and the brown regulator leads from terminals "F" and "L." Connect these two leads together.

NOTE: Carry out the test as quickly as possible and disconnect the green and brown leads from each other as soon as the test is finished. Be sure that the leads are insulated from the frame.

5. Start the engine and allow it to idle at 1,100-1,300 rpm. The voltmeter should read 14v DC or more. If less than this amount, either the alternator or the rectifier is defective.

CAUTION: Do not let the engine turn above idle speed or the electrical components may be damaged.

6. If the proper voltage reading was not obtained, check the rectifier as outlined in the following procedure. If the rectifier is satisfactory, check the alternator current output as follows.

7. Connect a 1 ohm-200W variable resistor, one lead to the rectifier white lead and the other to ground on the frame. Set the resistor at its maximum resistance and start the engine. Adjust the resistor to maintain a voltmeter reading of 14.5v, while gradually raising rpm to 5,000.

8. Stop the engine. Disconnect the voltmeter and the resistor lead to the rectifier white wire.

9. Connect an ammeter, set to the 30a DC range, to the variable resistor and to the rectifier white wire. This will put the meter, resistor, and rectifier in series. Be sure that all connections are tight. Start and run the engine at 5,000 rpm. The meter should read 13a DC. If the current reading is lower, the alternator is defective.

To determine which alternator component is faulty, proceed as follows:

10. Remove the right sidecover and disconnect the plug just below the regulator. With an ohmmeter, check the resistance between each of the three leads. Resistance should be 0.4-0.6 ohms. If any measurement shows infinite resistance, the armature has an open circuit and must be replaced.

11. With the highest meter range set to operate, measure resistance between each of the three leads and the frame (ground). Resistance should be infinite in each case. If a reading less than this is noted, the armature must be replaced as there is a short circuit.

12. Using the low range on the ohmmeter, check resistance between the field coil leads: green and black. It must be 4.8 ohms. An infinite reading indicates a break in the field coil, while a lower one indicates a short. In either case, replace the coil.

Rectifier

1. A full-wave rectifier with six diodes is used. An ohmmeter is used to check the rectifier.

2. Remove the left sidecover, disconnect the white rectifier lead from the battery and disconnect the rectifier black lead. The engine must be off.

3. Remove the right sidecover and disconnect the plug below the regulator.

4. Using the 10 or 100 ohm meter range, check resistance between the white lead and each yellow lead in turn, and then between the black lead and each yellow lead. Resistance measurements must be taken in both directions; that is, reverse the meter probes after each reading and take another.

Note the readings. If there is low resistance in one direction, there must be 10 times the amount when the leads are reversed. If any set of readings are either low or high in both directions, the rectifier must be replaced.

Regulator (Mechanical)

1. Remove the left sidecover and disconnect the 6-wire connector. Remove the headlight and disconnect the 9-wire connector in the shell.

2. Set a voltmeter to the 30v DC range and connect it across the battery. Start the engine and run it at 1,600 rpm. The meter should read 14-15v.

NOTE: As in the alternator test, the battery must be fully charged.

3. Increase engine speed. At 4,000 rpm, the meter reading should gain be 14-15v.

NOTE: Proceed to 4,000 rpm from a starting point of 1,600. If rpm returns to idle speed, increase it gradually to 1,600 and then to 4,000.

4. If voltage was not correct in both cases, proceed with the following checks:

NOTE: If the machine is still under warranty, the regulator should be replaced at this point.

5. Remove the right sidecover; disconnect the black, green, and brown regulator
