

HEPATOBIILIARY AND PANCREATIC DISORDERS

Anatomy and Physiology

1. The liver, one of the body's most important organs, has many metabolic and regulatory roles. However, its digestive system function is to produce bile for export to the duodenum.
2. The liver and gallbladder are accessory organs associated with the small intestine.
3. Bile is a fat emulsifier that breaks down fats into tiny particles to make them more readily digestible. Although the liver also processes nutrient-laden venous blood delivered to it from the digestive organs, this is a metabolic rather than a digestive role.

Gross Anatomy of the Liver

- a. The ruddy, blood-rich liver is the largest gland in the body, weighing about 1.4 kg (3 lb) in the average adult.
- b. Shaped like a wedge, it occupies most of the right hypochondriac and epigastric regions extending farther to the right of the body midline than to the left.
- c. Located under the diaphragm, the liver lies almost entirely within the rib cage, which provides
- d. some protection.
- e. The liver has four primary lobes. The largest, the right lobe, is visible on all liver surfaces and separated from the smaller left lobe by a deep fissure.
- f. Bile leaves the liver through several bile ducts that ultimately fuse to form the large common hepatic duct, which travels downward toward the duodenum.

Microscopic Anatomy of the Liver

- a. The liver is composed of sesame seed-sized structural and functional units called **liver lobules**. Each lobule is a roughly hexagonal (six-sided) structure consisting of plates of liver cells, or **hepatocytes**, organized like bricks in a garden wall.
- b. The hepatocytes also:
 - Process blood borne nutrients in various ways (e.g., they store glucose as glycogen and use amino acids to make plasma proteins)
 - Store fat-soluble vitamins
 - Play important roles in detoxification, such as ridding the blood of ammonia by converting it to urea

Composition of Bile

- ☐ Bile is a yellow-green, alkaline solution containing bile salts, bile pigments, cholesterol, triglycerides, phospholipids (lecithin and others), and a variety of electrolytes. Of these, only bile salts and phospholipids aid the digestive process.
- ☐ Bile salts, primarily cholic and chenodeoxycholic acids, are cholesterol derivatives.
 1. Their role is to emulsify fats—break them down into smaller pieces and distribute them throughout the watery intestinal contents, just as dish detergent breaks up a pool of fat drippings in a roasting pan.
 2. Bile salts physically separate large fat globules entering the small intestine into millions of smaller, more accessible fatty droplets that provide large surface areas for the fat-digesting enzymes to work on.
 3. Bile salts also facilitate fat and cholesterol absorption. In addition, they help solubilize cholesterol, both that contained in bile and that entering the small intestine in food.

Laboratory and Diagnostic Tests

1. **Hepatobiliary Scan**
 - a. Noninvasive nuclear medicine study (also referred to as HIDA scan based on the isotopes use)
 - b. Aids in the diagnoses of hepatobiliary disorders such as common bile duct obstruction, acute and chronic cholecystitis, bile leak, biliary atresia, and liver transplant function
 - c. A radioactive agent is administered I.V. It is taken up by the hepatocytes and excreted rapidly through the biliary tract.
