PROBLEM SOLUTIONS FOR CHAPTER 1 SOLUTIONS TO CHAPTER 1 PROBLEMS

3

- A translator converts programs in one language to another.
 - An interpreter carries out a program instruction by instruction.
 - A virtual machine is a conceptual machine, one that does not exist.
- It is possible, but there are problems. One difficulty is the large amount of code produced. Since one ISA instruction does the work of many microinstructions, the resulting program will be much bigger. Another problem is that the compiler will have to deal with a more primitive output language, hence it, itself, will become more complex. Also, on many machines, the microprogram is in ROM. Making it user-changeable would require putting it in RAM, which is much slower than ROM. On the positive side, the resulting program might well be much faster, since the overhead of one level of interpretation would be eliminated.
- During the detailed design of a new computer, the device and digital logic levels of the new machine may well be simulated on an old machine, which puts them around level 5 or 6.
- Each level of interpretation slows down the machine by a factor of n/m . Thus, the execution times for levels 2, 3, and 4 are kn/m , kn^2/m^2 , and kn^3/m^3 , respectively.
- Each additional level of interpretation costs something in time. If it is not needed, it should be avoided.
- You lose a factor of n at each level, so instruction execution times at levels 2, 3, and 4 are kn , kn^2 , and kn^3 , respectively.
- Hardware and software are functionally equivalent. Any function done by one can, in principle, be done by the other. They are not equivalent in the sense that to make the machine really run, the bottom level must be hardware, not software. They also differ in performance.
- Not at all. If you wanted to change the program the difference engine ran, you had to throw the whole computer out and build a new one. A modern computer does not have to be replaced because you want to change the program. It can read many programs from many CD-ROMs.
- A typical example is a program that computes the inner product of two arrays, A and B. The first two instructions might fetch A[0] and B[0], respectively. At the end of the iteration, these instructions could be incremented to point to A[1] and B[1], respectively. Before indexing and indirect addressing were invented, this was done.
