

Study Guide: Distributed Systems - Processes

Key Concepts

- **Process:** A program in execution, managed by the operating system. It has its own context, including CPU registers, program counter, memory maps, and open files. The OS creates a virtual processor for each running program (process), providing isolation and transparency.
- **Thread:** A lightweight subprocess that runs within a process. Multiple threads can exist within a single process and operate independently, sharing the process's resources.
- **Virtualization:** The creation of a virtual version of something, such as hardware, an operating system, or network resources. In distributed systems, it provides abstraction and can enable the execution of different environments on the same physical infrastructure.
- **Client/Server Organization:** A fundamental architectural pattern where a client process requests services from a server process. This model underpins much of distributed computing.
- **Code Migration:** The transfer of executable code from one machine to another. This can be done for various reasons, such as improving performance, accessing specific resources, or dynamically configuring clients.
- **Process Context:** The minimal set of information about a process that the operating system needs to save and restore to allow the process to be interrupted and later resumed correctly.
- **Virtual Processor:** An abstraction created by the operating system that gives each running program the illusion of having its own dedicated CPU.
- **Context Switching:** The process of saving the state of one process or thread and loading the saved state for another, allowing the CPU to be shared among multiple execution units.
- **Kernel-level Threads:** Threads managed directly by the operating system kernel.
- **User-level Threads:** Threads managed by a user-level threads library within a process, without direct kernel involvement for scheduling and context switching.
