Organic Solvent Nanofiltration in the Peptide Industry Patrizia Marchetti,2013 In recent years the application of membrane technology to molecular separation processes has stimulated interest and showed great potential in a number of

industrial fields Ultrafiltration membranes have been successfully applied to downstream separation of therapeutically active peptides to overcome some of the limitations of the conventional techniques in terms of costs scale up selectivity and solvent recovery In this research project Organic Solvent Nanofiltration of peptide solutions is studied and this understanding is applied to the development of innovative membrane based purification strategies for industrial case studies Basic understanding of transport mechanisms was approached by investigating solvent transport through ceramic nano and ultrafiltration membranes and developing a predictive phenomenological model for the transport of solvents and solvent mixtures Effects of solvent membrane interactions strongly affected the solvent permeation through nanofiltration membranes while they were found to be negligible in the ultrafiltration range The effect of the organic solvent on the permeation of neutral and charged solutes monovalent salts a small molecule and peptides in organic water mixtures was studied with particular attention to the role of preferential solvation in the solvent mixture It was found that the solvent composition and the complex association of counter ions and buffers highly affect membrane permeation and rejection of organic molecules It is proposed that all these components change the relative solute membrane affinity Since permeation of peptides in organic water mixtures is affected by complicated matrices of input parameters a Design of Experiment approach was proposed to efficiently investigate the nanofiltration of model peptides in acetonitrile water solutions Statistical models for solvent flux peptide and ion rejection were obtained by Analysis of Variance and interpreted from a phenomenological point of view The statistical models were used to assist process development for two industrial case studies 1 concentration and salt solvent exchange of a first therapeutic peptide were optimised based on the integration of the statistical DoE models with the process simulation for concentration and diafiltration 2 the nanofiltration assisted synthesis of a second therapeutic peptide based on the coupling between nanofiltration and reaction in one unique process was developed and compared to the established process by techno economical analysis The so called Reactive Peptide Nanofiltration was found to be advantageous in terms of economics efficacy impact on the market and on the environment In conclusion nanofiltration was found to be a solid and competitive technique for application to peptide processes On the basis of the results of this research Lonza decided to invest in a new nanofiltration plant for the downstream of peptides with ceramic membranes The advantages of nanofiltration technology in terms of development of more efficient materials stable in critical solvents and harsh acid basic conditions improvement of membrane performances selectivity lifetime and integration of nanofiltration with other techniques in hybrid processes seem therefore promising in overcoming the hesitancy of industries to modify the established processes and invest in new nanofiltration plants by making the payback period for the return of investment more attractive It is plausible to think that this technology will shortly become a primary choice for new separation and purification processes

Liu,2003 Study of the Separation by Organic Solvent Nanofiltration of Diluted Solutes Using Commercial, Dense and Porous Membranes and Their Derivatives by Deposition of Polyelectrolyte Nanolayers Mahbub Morshed,2019 The objective of this study was to improve the OSN separation performance of commercial membranes for metathesis applications in which highly diluted catalysts are used In this work commercial polymeric membranes were first studied to characterize their performance in organic media using very dilute solute solvent binary mixtures Based on a literature review it was shown that the PERVAP4060 membrane of which PDMS is the dense active layer was a promising candidate for organic solvent nanofiltration OSN As a porous membrane the AMS and PAN commercial supports have also been taken into account In this study we considered the modification on the surface to improve the separation properties of polymeric OSN membranes Ar O₂ plasma and or polyelectrolytes multilayers were used for the preparation of new prototype membranes Unmodified and modified membranes were tested under OSN conditions using binary feed mixtures Several highly dilute solutes organophosphorus ligand R BINAP phase transfer catalyst ToABR and linear alkanes have been studied Both R BINAP and ToABR were used in the range of 0.0001 to 0.5% by weight and most experiments were subsequently performed with 0.05% solute concentrations in toluene It has been shown that PDMS can retain 80% R BINAP and about 93% ToABr in toluene After modification by the LBL deposition the rejection is improved with the modified PERVAP4060 membranes leading to an 88% rejection of R BINAP with a deposit of 10 PAH PSS polyelectrolyte bilayers at the surface and this rejection being able to reach 95% when the number of bilayers is 20 ToABr rejection increases to 97% with the ten bilayered membranes The performance of the membrane was studied under different pressures of between 1 and 40 bar the high rejection still observed in these OSN conditions strongly supports a solution diffusion transfer mechanism through the PDMS The treatment of ternary mixtures mimicking the catalyst solute solvent mixture corresponding to the hydroformylation has also been studied no evidence of coupling was detected and the highest retention remained unchanged On the other hand the improvement of the rejection also observed from the porous membranes after modification The rejection of C₄₄ in the AMS was reached 75% after modification by 10 bilayers of PDDA PSS whereas it was only 25% before modification In the modified PAN the rejection of the solutes obtained is in the range of 37 to 50% whereas it was only 3 to 7% by weight before modification The disadvantage of the porous membrane however is the sharp decrease in flux after the deposition of the multiple layers

Dario R. Machado,Ṭekhniyon, Makhon ṭekhnologi le-Yiśra'el. Fakultah le-handasah khimit,1998 **The Influence of Temperature on Ion Transport in Nanofiltration Membranes** Yagnaseni Roy,2018 Nanofiltration NF is a pressure driven membrane based solution treatment technology similar to reverse osmosis RO The niche set of applications for NF includes those requiring selectivity between monovalent ions and multivalent ions Incoming streams to be treated can occur over a wide range of temperature usually between 20 100 C The advantage of operating NF at higher temperatures is increased water recovery while the key drawback is diminished salt retention Although the change of these performance metrics is widely reported in literature few sources explain the causative mechanisms Temperature variation of the mobilities of both solute and solvent species the solute diffusivity and solvent viscosity are well studied and are used to explain changes in transport through the membrane in most literature However NF membranes are defined by several structural and charge based properties which are likely to be affected by temperature This thesis elucidates the effect of individual membrane properties and mobilities on NF permeate quality and finally compares sets of parameters on the extent to which they explain the change in NF selectivity with temperature change Modeling results show that neither membrane parameter changes nor mobilities can alone explain selectivity changes with temperature With increasing pressure however the net effect of membrane parameters increasingly overshadows that of the mobilities As mentioned previously NF is used particularly for

monovalent multivalent ion separations The study of fractionation involving separation of sodium chloride from sodium sulfate is one such application and is often conducted between 20 50 C Previous studies do not indicate whether selectivity between the charged species improves or deteriorates at higher temperature In this thesis a selectivity metric M is introduced and an analytical framework is established to explain its variation with temperature variation as well as other membrane and operating parameters The conclusion is that selectivity decreases at higher temperature which can be mitigated by design focus on enhanced charge acquirement by the membrane at elevated temperature The final segment of this work introduces a common modeling framework for pressure driven NF and RO and osmotically driven membrane processes forward osmosis FO to identify both similarities and dissimilarities in salt transport mechanisms RO and FO membranes are traditionally considered non porous membranes while NF membranes are known to possess nanometer sized pores However experimental and spectroscopy results in the past decade report detection of pores in RO and FO membranes The modeling results in this thesis show that all three membranes can be modeled as porous the key distinction being that the pressurized modes allow salt water transport coupling
