Thermal Equilibrium

Types of Heat Transfer

Temperature differences exist in objects that are all around us - from the ice cream cone we eat to the road down the hot concrete sidewalks to the hot summer air as we wait for the air-conditioned bus to arrive. Heat can move in three different ways: radiation, convection, and conduction.

Conduction
As an object is heated, the particles in it vibrate more vigorously. The heat energy is then passed on to the next particle. This process is called conduction. When heat is transferred from one object to another by direct contact, it is called conduction. For example, the handle of a metal spoon becomes hot when the spoon is placed in a hot liquid.

Particle Arrangement

To understand how thermal energy moves, we must first consider that all matter is made up of particles. Everything we know is made of tiny particles, from the rocks on our feet, to the air that we breathe, to our favorite gaming console.

On Earth, all matter exists in three main phases, or forms - solids, liquids, and gases. Phase is determined by the particle arrangement of a substance.

Figure 1: Solid

The particles that make up **solids** are packed together very tight. The particles are held together too strongly to allow movement from place to place but the particles do vibrate in their spot. If you put a solid into a container, it will not take the shape of its container because the particles are not free enough to move around. When heat is added, the particles of a solid will vibrate faster and spread apart a bit. Solids have definite volume and definite shape.

The particles that make up **liquids** are not as tightly packed as solids. There is a bit more space between each particle and they move with random motion throughout a container. The particles can move in all directions and collide with each other. When heat is added the particles move faster and spread further apart. Liquids have a definite volume but no definite shape.
