Effects of Omnivorous Crayfish on Fish Populations and the Structure of Littoral Communities Nathan Jeffrey Dorn, 2003 **Fine Structure of Crayfish Optic**

Ganglia, 1967 **Fine Structure of Crayfish Optic Ganglia** Homer B. Latimer, 1967 **Crayfish** Felipe Bezerra Ribeiro, 2020 Crayfish are one of the most iconic freshwater crustacean groups of the world. The wide range of biological adaptations of the freshwater crayfish to the limnetic ecosystems is surprising as is there is high potential of some taxa to become invasive species. There is a constant growing interest in develop research with freshwater crayfish. They can be an important food source in several countries, the aquarium pet trade and cultural importance in addition to the presence of several imperiled species. This book brings important reviews of some aspects of diversity, biological features, evolution, habitat characteristics, behavior and conservation strategies of freshwater crayfish including native taxa especially endemic from South America, New Guinea and North America and non indigenous species. In South American new species have been discovered in recent years and are classified in threat categories indicating the need of more studies regarding taxonomy and conservation. For New Guinean species data about their exploitation by humans and further perspectives about the improvement of conservation practices are presented. In relation to the North American crayfish this book brings information about some aspects of biology and behavior of the burrowing species *Procambarus acanthophorus*. A global assessment and future perspectives for all alien crayfish species are also presented in this book. Regarding the partenogenetic marbled crayfish *Procambarus virginalis* the book brings an extensive review covering aspects of detection history, biology, ecology, evolution, systematics and utilization of this species in the world. In addition an overview of integrative taxonomy studies and cryptic diversity in crayfish is also presented.

Structure and Function of the Crayfish Phasic Flexor Neuromuscular System Thomas H. Brown, 1976 **The Fine Structure of the Arthrobranch of the Crayfish, *Pacifastacus leniusculus* Dana, with Special Reference to Active Ion Uptake** Howard Curtis Morse, 1967 The gills of an Oregon crayfish *Pacifastacus leniusculus* Dana were examined with histological and histochemical techniques and their fine structure was investigated by electron microscopy. Special attention was given to the structural basis of active ion uptake. The histology of these gills was the same as that of other crayfish species described by earlier workers. There are basically three cell types: hypodermal cells of stalk and tubules, connective tissue cells and nephrocytes. In addition two cell products are present: the cuticle and connective tissue fibers. The hypodermal cells of the stalk combine into a solid sheet underlying the cuticle while those of the tubules are pear shaped with a body neck and cytoplasmic sheet. The body containing the nucleus continues into a smaller neck which flares out into the flattened sheet running perpendicular to the length of the neck but parallel to and closely apposed to the cuticle. Nephrocytes are large multinucleate phagocytes attached to the walls of efferent vessels of the stalk and tubules as well as the stalk mantle canal. These cells are found to contain much acid phosphatase activity. Electron microscopy reveals that the nephrocytes are covered on the surface with a system of long microvilli which drape over cisternae. The plasma membrane delimits the inner surface of the cisternae on which numerous micropinocytotic vesicles can be seen in favorable sections. Within the cytoplasm are dense bodies, vesicles resembling micropinocytotic vesicles peripheral

vacuoles and large central vacuoles Dictyosomes and large mitochondria with few cristae and of low electron density are occasionally seen It is suggested that material which is phagocytized by micropinocytosis may be combined with dense bodies which may contain lytic enzymes to form peripheral and thence central vacuoles where intracellular digestion would occur The surface position of the hypodermal cells of the stalk or tubules makes them both likely candidates for a role in active ion uptake The apparent lesser density of the tubule cuticle and greater abundance of mitochondria in the pear shaped hypodermal cells of the tubules compared with the stalk cuticle and hypodermis indicates that the pear shaped cells are more likely involved in such a process Chloride localization with silver salts at the organ level indicates that the cuticle of tubules arising from the base and midsection of a gill stalk are strikingly more ion permeable than tubules from the tip the stalk or other parts of the whole body surface This permeability difference correlates with a fine structure difference in tubular cuticle and pear shaped cells depending upon their location The cytoplasmic sheet of pear shaped cells from the gill tip is thinner and may contain fewer mitochondria while the cuticle in this region has an epicuticle of higher electron density Chloride localization with silver acetate at the fine structure level somewhat suggests the same base to tip differentiation and shows localization of the precipitated silver at the outer membrane of pear shaped cells and cytoplasmic sheet This suggests that the chloride pump is located in the outer membrane of the pear shaped cells and cytoplasmic sheet located in the tubules of the lower half of the gills
