

Introduction

As you have noted in previous exercises, storing program data permanently can be achieved using text files. Text files are a good and convenient way of storing small amounts of structured block data, like passwords and login details, however when processing more complex groups of structured datasets it becomes cumbersome and slow. Normally, in data-processing systems, we use what is known as **relational database** to store data. That is, data stored in **Tables**, where each table is related to one another. To extract data from these tables we use **Structured Query Language (SQL)**. This is a type of language specifically designed to insert, read, process and update data stored in tables. The program which compiles and executes SQL code is called the **SQL engine**. This program can either be stored on your desktop computer or a server.

If you imagine a typical setup:

You may have many programs in different languages all using the same SQL to send to the engine. The engine then retrieves or inserts from the main database with results sent back

Create Database

Before embarking on a database system, we first need to create the backend, that is the database itself. In Python, you first import `sqlite3` and make a connection to the database file, if it doesn't exist the file is created.

1

```

1 import sqlite3
2 from sqlite3 import Error
3
4 filename = "Example_database.db"
5
6 try:
7     conn = sqlite3.connect(filename)
8     print (sqlite3.version)
9 except Error as e:
10    print (e)
  
```

Figure 1: Connecting to SQLite database.

- LINE 1** imports the `sqlite3` module (should be part of the Python install).
- LINE 2** imports error reporting. Useful for printing errors to help with debugging.
- LINE 4** database filename. Without specifying the folder path, this will be in the same directory as this program.
- LINE 6 & 7** We use the `try`, `error` commands. This is necessary as when you connect to the database there may be errors such as the file not existing or incorrect file format, which we need to catch rather than terminating the program. Notice we use the `Error` library import to output the error.
- LINE 7** create the connection and instantiate as `conn` object.
- LINE 8** output the version. This is just for debugging purposes.
